

Heredity and the Nature of Man

9 The Genetics of Man

Humiliating as it may seem, our understanding of inheritance in man is founded heavily on what was discovered in other organisms such as peas, *Drosophila*, corn, mice, *Neurospora*, and more recently, microorganisms. Man is not a very good organism for genetic research. His generation time is much too long—most geneticists would be dead before an F_2 appeared. He has so many chromosomes, 23 pairs, that it is extremely difficult to detect linkage groups. He would be most expensive to maintain as a laboratory animal and some of his mores prevent sound experimentation. For example, abundant offspring, brother-sister matings to develop highly homozygous strains, backcrosses of F_1 individuals to members of the parent generation, crosses based on the design of the experiment rather than emotion are not *de rigueur*. Matings occur in man for many reasons, all thought excellent at the time, but rarely, if ever, is one of the reasons the advancement of genetics. But thanks to more amenable organisms and the near-universality of genetic principles, a firm foundation for a genetics of man has been laid. Nevertheless, many of the statements that will be made in this chapter are more in the nature of probable hypothesis than of fact. Many patterns of inheritance, originally thought to be clear examples of autosomal recessives, autosomal dominants, sex-linked genes, and so on, have been shown by later data to be more complex.

A human geneticist attempts to deduce genotypes from the observed phenotypes of parents and offspring. He has developed a symbolism that allows one to easily recognize males, females, parents, offspring, and
